Functional genomics + Data mining

BCH364C/391L Systems Biology / Bioinformatics – Spring 2015 Edward Marcotte, Univ of Texas at Austin

Functional genomics

= field that attempts to use the vast data produced by genomic projects (e.g. genome sequencing projects) to describe gene (and protein) functions and interactions.

Focuses on dynamic aspects, e.g. transcription, translation, and protein—protein interactions, as opposed to static aspects of the genome such as DNA sequence or structures.

We're going to first learn about clustering algorithms & classifiers

We're going to first learn about clustering algorithms & classifiers

Clustering = task of <u>grouping</u> a set of objects in such a way that objects in the same group (a **cluster**) are more similar (in some sense) to each other than to those in other groups (clusters).

Adapted from Wikipedia

We're going to first learn about clustering algorithms & classifiers

Classification = task of <u>categorizing</u> a new observation, on the basis of a training set of data with observations (or instances) whose categories are known

Adapted from Wikipedia

Let's motivate this with an example:

Distinct types of diffuse large B-cell lymphoma identified by gene expression profiling

Nature 2000

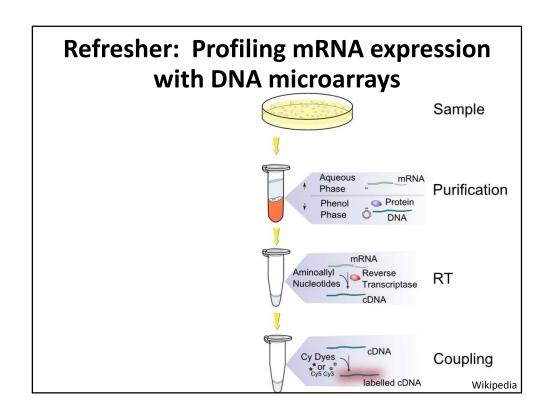

"Diffuse large B-cell lymphoma (DLBCL), the most common subtype of non-Hodgkin's lymphoma ... is one disease in which attempts to define subgroups on the basis of morphology have largely failed..."

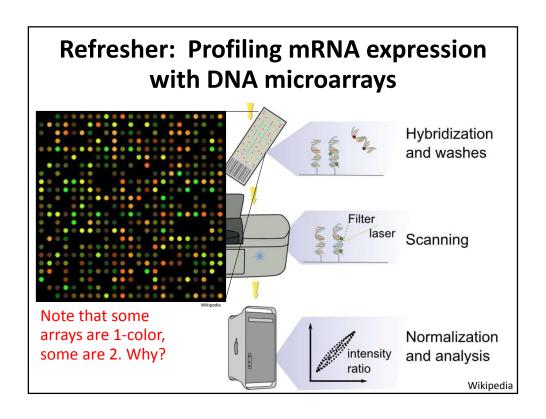

"DLBCL ... is clinically heterogeneous: 40% of patients respond well to current therapy and have prolonged survival, whereas the remainder succumb to the disease.

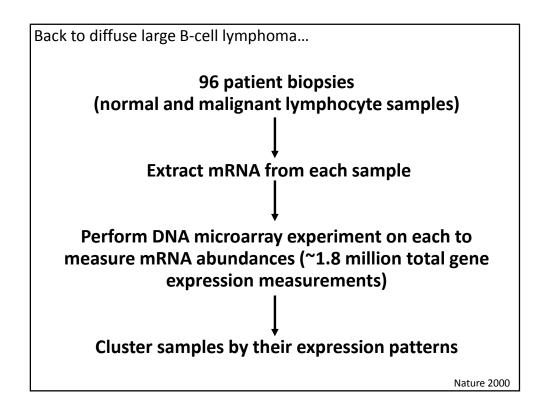

We proposed that this variability in natural history reflects unrecognized molecular heterogeneity in the tumours."

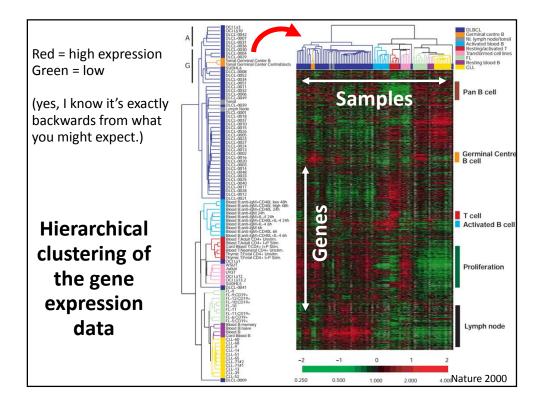

Nature 2000

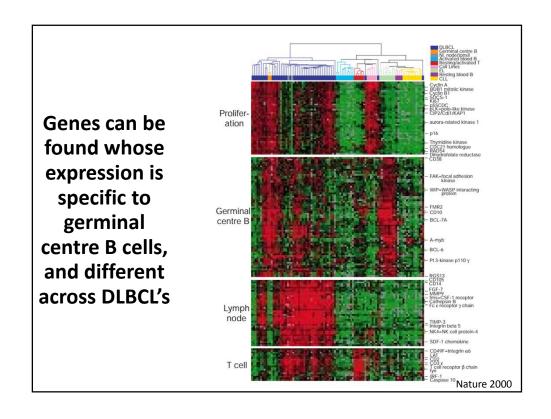

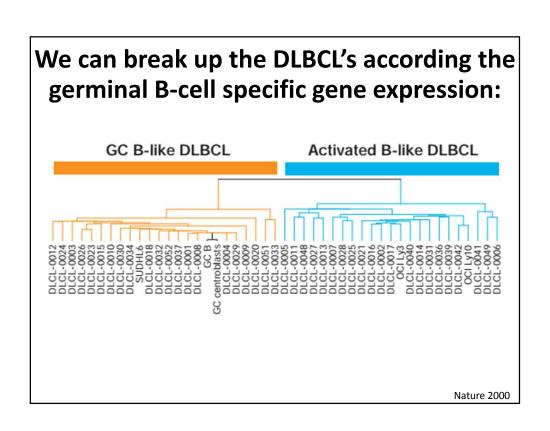

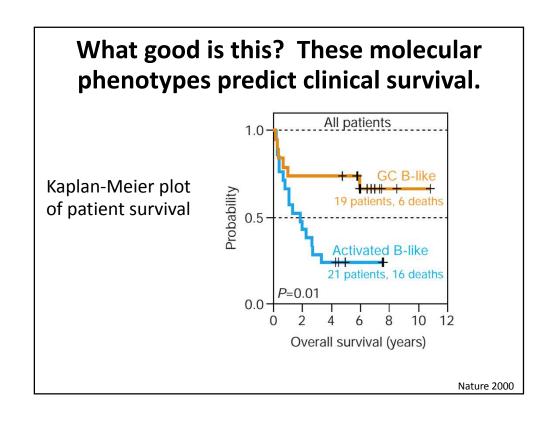

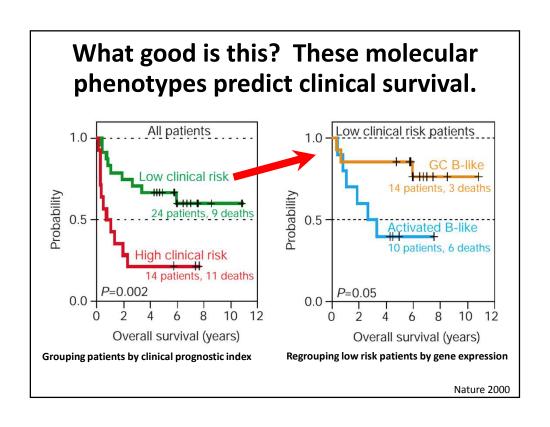

Gene expression, and other molecular measurements, provide far deeper phenotypes for cells, tissues, and organisms than traditional measurements

Now, tons of work using these approaches to diagnose specific forms of disease, as well as to discover functions of genes and many other applications

So, how does clustering work?

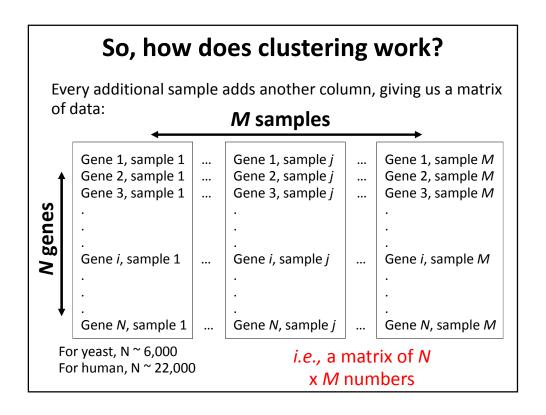

First, let's think about the data, e.g. as for gene expression. From one sample, using DNA microarrays or RNA-seq, we get:

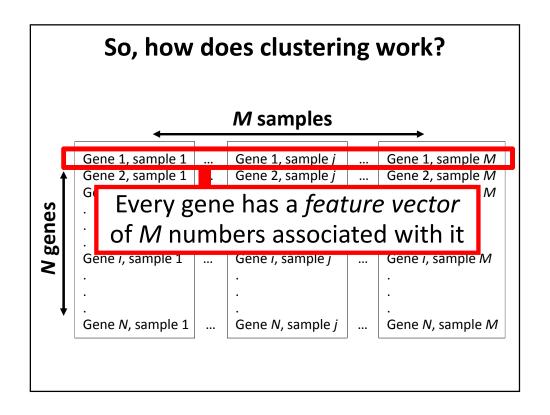

Expression level of gene 1
Expression level of gene 2
Expression level of gene 3

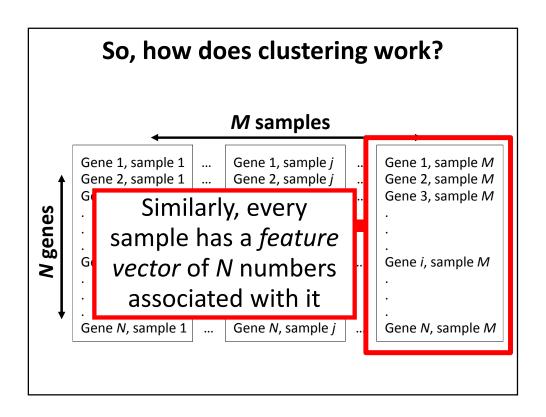

.
.
.
Expression level of gene i
.
.
Expression level of gene i
.
.
Expression level of gene N

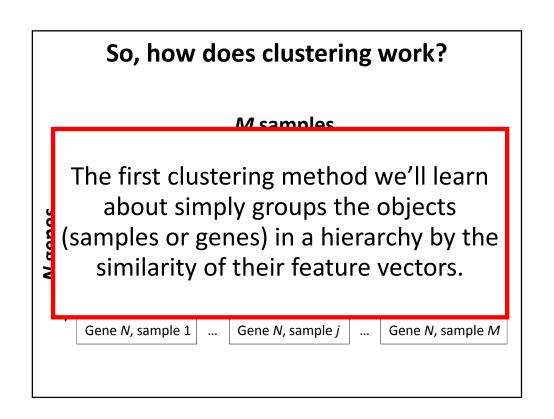

i.e., a vector of *N* numbers

For yeast, N ~ 6,000 For human, N ~ 22,000

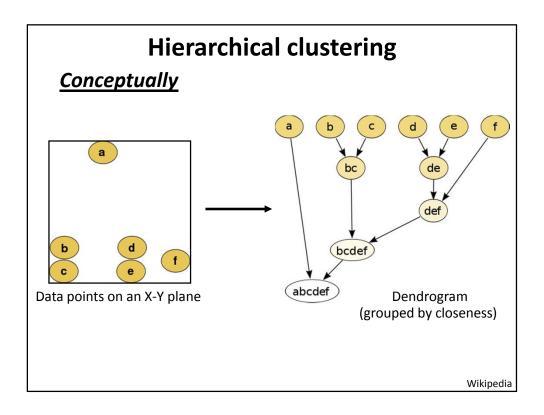

A hierarchical clustering algorithm

Start with each object in its own cluster

Until there is only one cluster left, repeat:

Among the current clusters, find the two
most similar clusters
Merge those two clusters into one

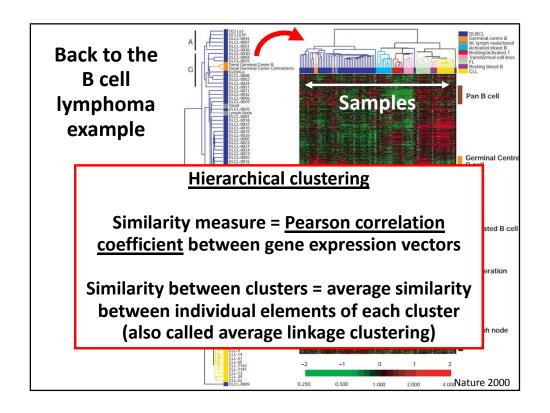

We can choose our measure of similarity and how we merge the clusters

We'll need to measure the similarity between feature vectors. Here are a few (of many) common distance measures used in clustering.

Names	Formula
Euclidean distance	$ a - b _2 = \sqrt{\sum_i (a_i - b_i)^2}$
Manhattan distance	$ a - b _1 = \sum_i a_i - b_i $
cosine similarity	$\frac{a \cdot b}{\ a\ \ b\ }$

Wikipedia

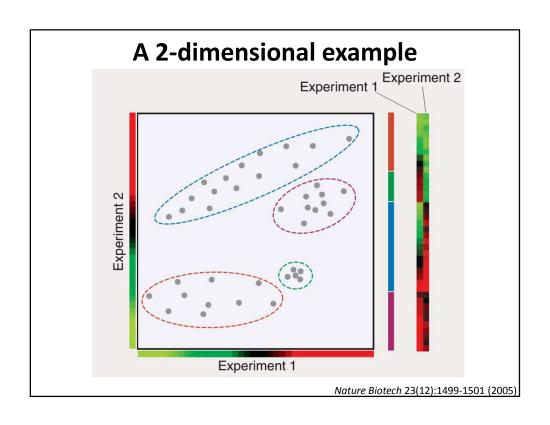

K-means clustering is a common alternative clustering approach

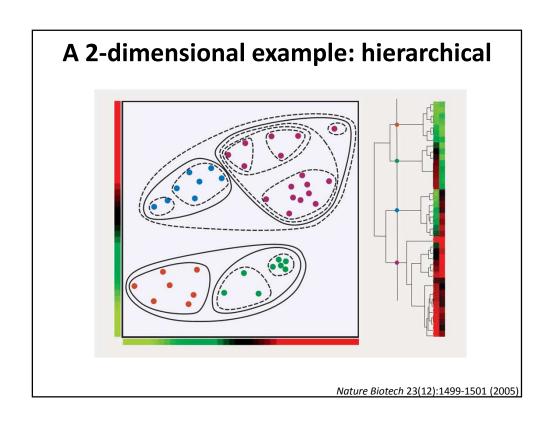

mainly because it's easy and can be quite fast!

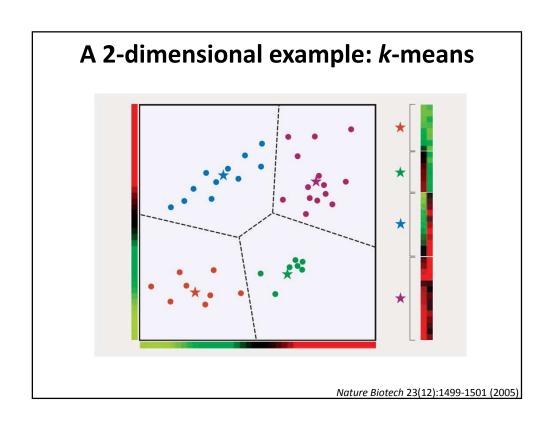

The basic algorithm:

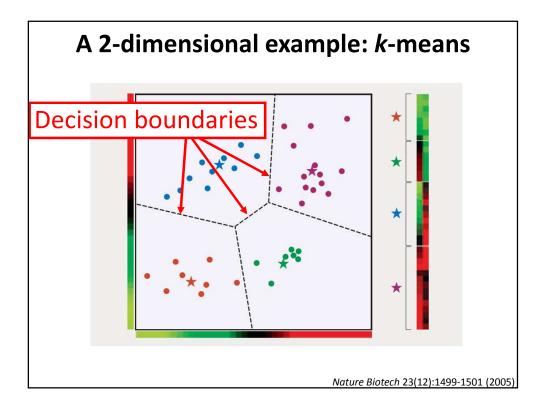

- 1. Pick a number (k) of cluster centers
- 2. Assign each gene to its nearest cluster center
- 3. Move each cluster center to the mean of its assigned genes
- 4. Repeat steps 2 & 3 until convergence

See the K-means example posted on the web site

Some features of K-means clustering

- Depending on how you seed the clusters, it may be stochastic. You may not get the same answer every time you run it.
- Every data point ends up in exactly 1 cluster (so-called hard clustering)
- Not necessarily obvious how to choose k
- Great example of something we've seen already: <u>Expectation-Maximization (E-M) algorithms</u>

EM algorithms alternate between assigning data to models (here, assigning points to clusters) and updating the models (calculating new centroids)

Some features of K-means clustering

- Depending on how you seed the clusters, it may be stochastic. You may not get the same answer every time you run it.
- Every data point ends up in exactly 1 cluster (so-called hard clustering)
- Not necessarily obvious how to choose k

Let's think about this aspect for a minute.

Why is this good or bad?

How could we change it?

updating the models (calculating new centrolus)

a to

k-means

The basic algorithm:

mo

- 1. Pick a number (k) of cluster centers
- 2. Assign each gene to its nearest cluster center
- 3. Move each cluster center to the mean of its assigned genes
- 4. Repeat steps 2 & 3 until convergence

Fuzzy k-means

The basic algorithm:

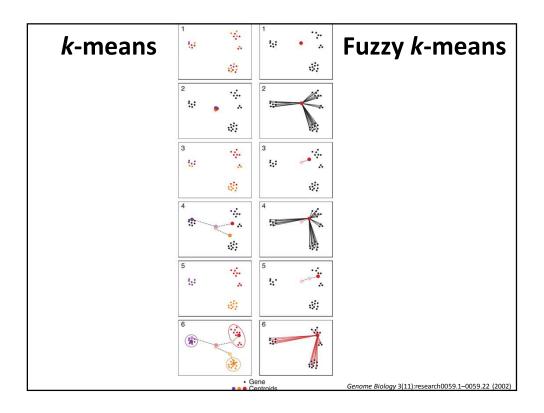

- 1. Choose k. Randomly assign cluster centers.
- 2. Fractionally assign each gene to each cluster:

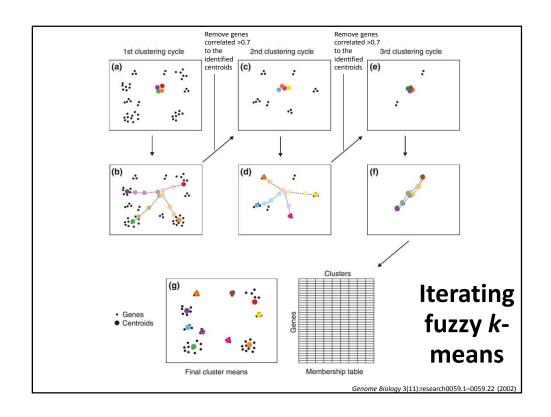

e.g. occupancy
$$(g_i, m_j) = e^{-||g_i - m_j||^2}$$

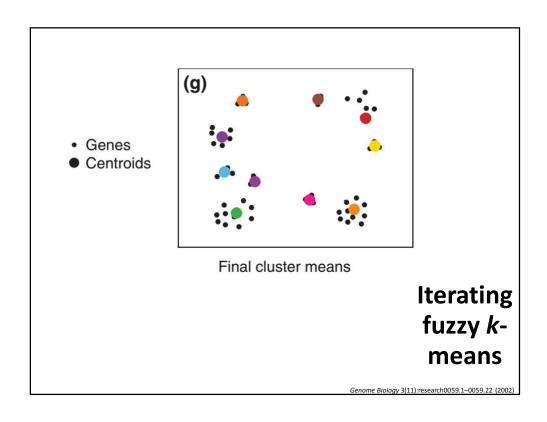

$$\sum_j e^{-||g_j - m_j||^2}$$
Note: $||x||$ is just shorthand for the length of the vector x .
$$g_i = \text{gene i}$$

$$m_i = \text{centroid of cluster j}$$

- 3. For each cluster, calculate weighted mean of genes to update cluster centroid
- 4. Repeat steps 2 & 3 until convergence

A fun clustering strategy that builds on these ideas: Self-organizing maps (SOMs)

- Combination of clustering & visualization

Invented by Teuvo Kohonen, also called Kohonen maps

Dr. Eng., Emeritus Professor of the Academy of Finland; Academician

A fun clustering strategy that builds on these ideas: Self-organizing maps (SOMs)

SOMs have:

your data (points in some high-dimensional space) a grid of nodes, each node also linked to a point someplace in data space

- 1. First, SOM nodes are arbitrarily positioned in data space. Then:
- 2. Choose a training data point. Find the node closest to that point.
- 3. Move its position closer to the training data point.
- 4. Move its grid neighbors closer too, to a lesser extent.

Repeat 2-4. After many iterations, the grid approximates the data distribution.
