What is Principal Component Analysis? What does it do?

So, first let's build some intuition.

What is Principal Component Analysis? What does it do?

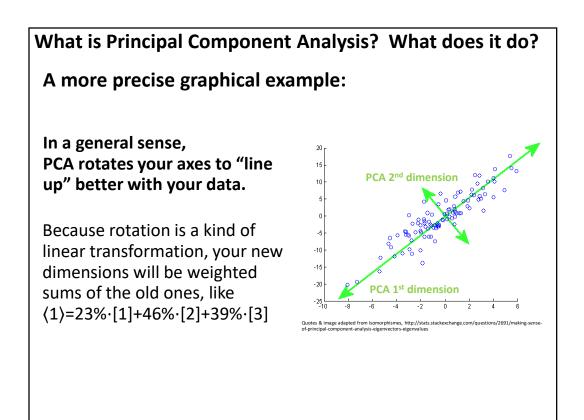

A general (and imprecise) political example:

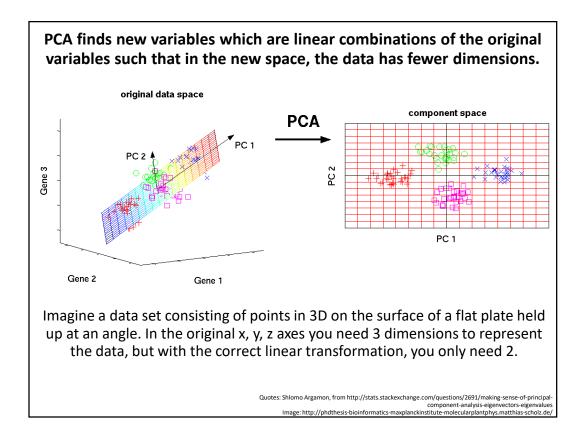

Suppose you conduct a political poll with 30 questions, each answered by 1 (*strongly disagree*) through 5 (*strongly agree*). Your data is the answers to these questions from many people, so it's 30-dimensional, and you want to understand what the major trends are.

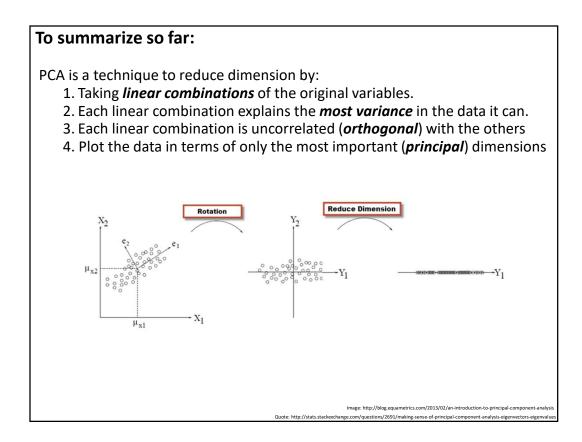

You run PCA and discover 90% of your variance comes from one direction, corresponding not to a single question, but to a specific weighted combination of questions. This new hybrid axis corresponds to the political left-right spectrum, *i.e.* democrat/republican spectrum.

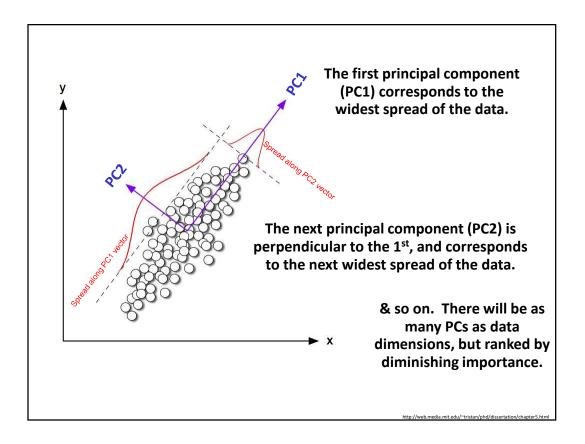

Now, you can study that, or factor it out & look at the remaining more subtle aspects of the data.

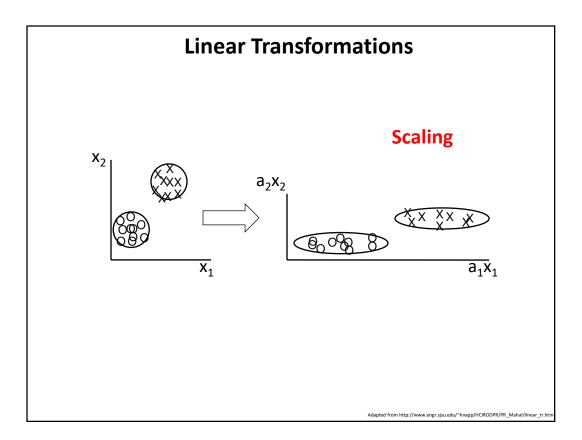

So, PCA is a method for discovering the major trends in data, simplifying the data to focus only on those trends, or removing those trends to focus on the remaining information.

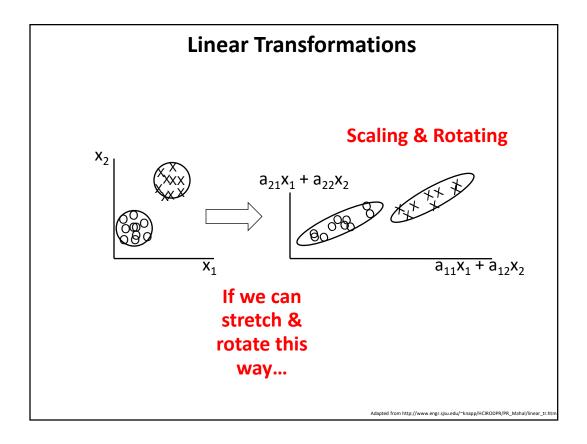

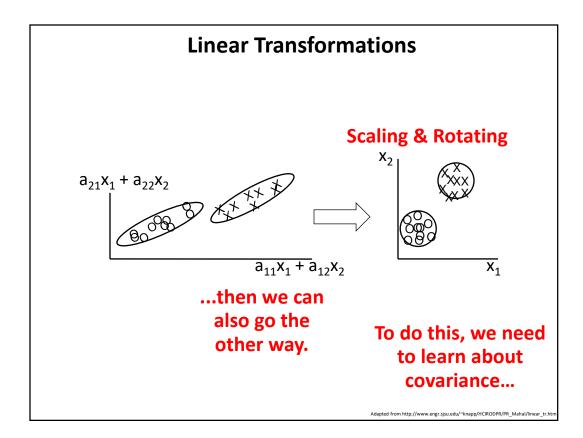

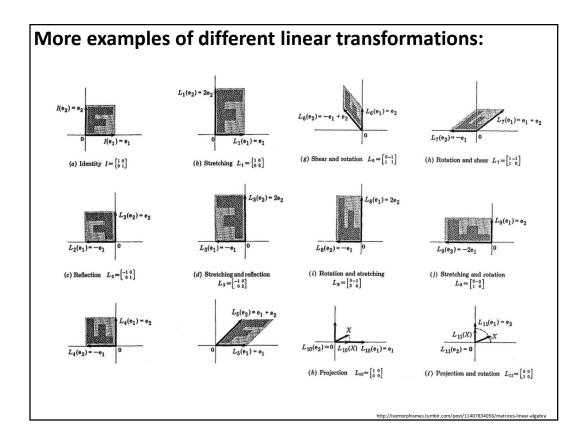

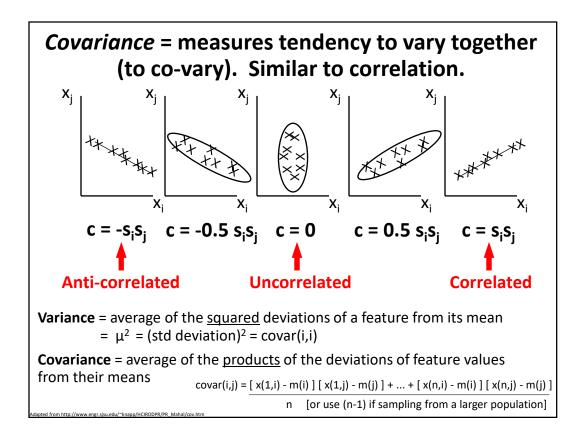

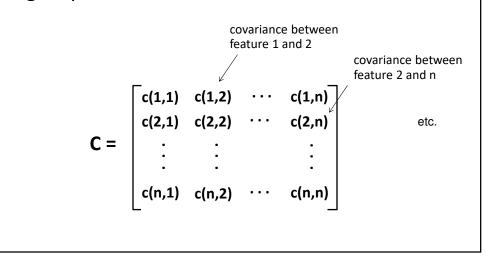

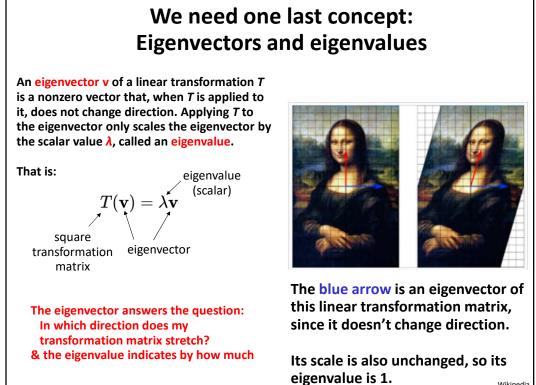

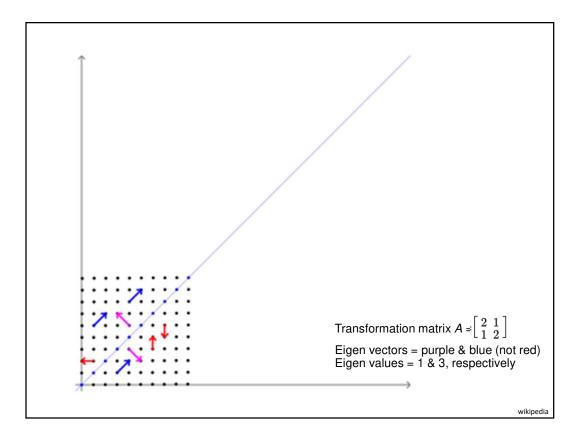

All of the **covariances** c(i,j) between features can be collected together into a **covariance matrix** C.

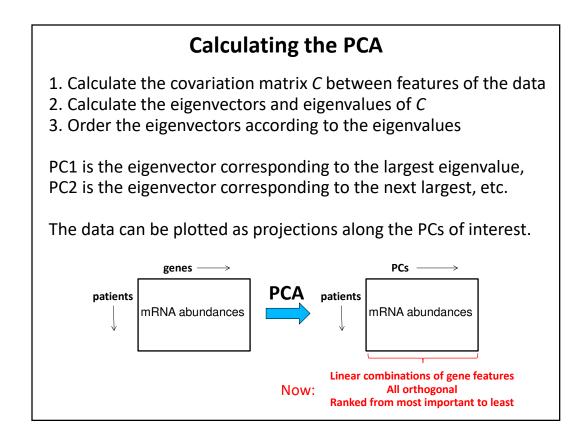

This summarizes all of the correlation structure among all pairs of features.

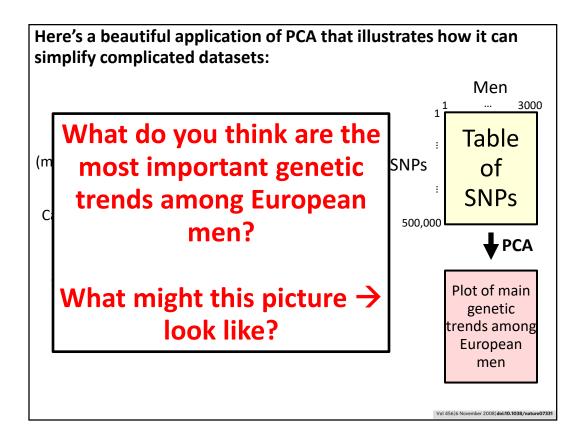

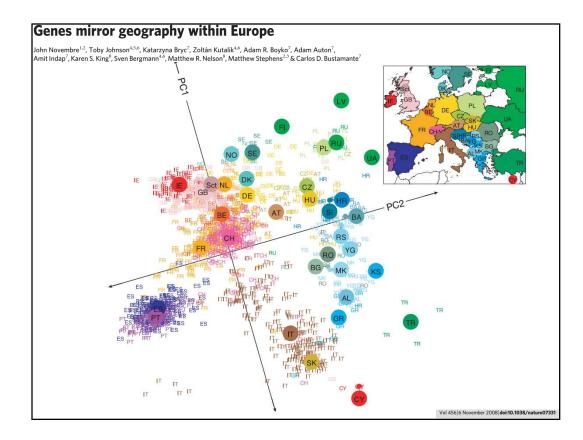

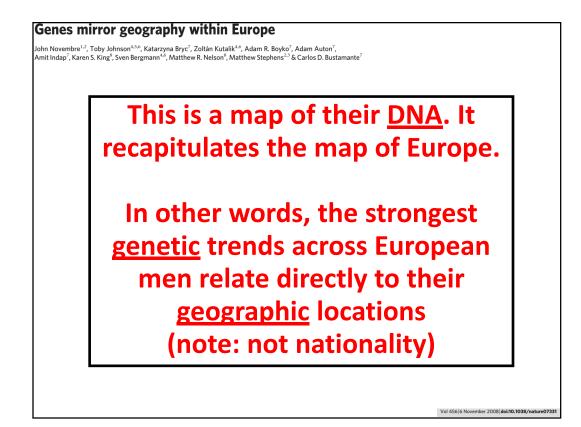

Wikipedia

	PCA	tSNE & UMAP
Linear/non-linear	Linear	Non-linear
Are local & global structure preserved?	Preserves global structure (variance, general trends), but local depends on dimensionality	Preserve local neighborhoods (thus good at clustering similar elements), can be quite poor on global structure
Suitable for subsequent data analyses on projected data, projection of new data points in the reduced dim space, feature selection, noise reduction, etc?	Yes	Not generally, primarily just visualization
Are embeddings interpretable in terms of the original features?	Yes	No
Tunable parameters?	No (except the # dim)	Yes
